of the density. It is assumed that the total annihilation occurs at $\Delta 1/1 = 1.5\%$. During the expansion, the tension inside the matter increases gradually, leading to the general annihilation at $t=3260$ sec. In the case of an earlier break-off at considerably reduced tension the gap widens during the expansion. A sound wave emerges from this gap and propagates into the matter, nullifying the stress at a distance of 100 km. Solid hydrogen disintegrates into pieces of ~ 100 km in diameter and 10^{20} g. On condition that the fluctuations occur at $\rho_0 = 0.01$, $\Delta \rho/\rho$ will reach the order of magnitude unity if the density corresponds to such a value ρ_1 that $2 \cdot 10^{-7} (\rho_1/\rho_0)^{-1/3} = 1$. ρ_1 is then equal to 10^{-22} . This density is reached after $3 \cdot 10^6$ years. The mechanism here described is not sufficient for the origination of galactics. The strong perturbances during the origination of stars and the onset of nuclear reactions within them seem, however, to further the gravitation-induced instability in the expansion of the universe. The present paper offers no complete description of how stars are created; its most important result is the proof that the restriction to molecular fluctuations is forbidden.

"Kislorod" No 3

In present day air-distributing apparatus regenerative equipment is widely used. It is important to determine their capacity and dimensions. In this article the author attempts to define the size of the regenerative equipment which is necessary for efficient operation. Well illustrated, with diagrams of proposed equipment and tables of data obtained from experiments. For calculating the heat

transfer coefficient in regenerative nozzles with spiral apertures the author gives a formulae, which shows a relation between Nusselt's (Nu) criterion and Reynold's (Re) criterion with respect to the length and width of the air channel. Formula: $Nu = 3.7 + 0.96 \left(\frac{1}{d}\right) - 1.43 \cdot Re$. This article appears to be a continuation of an earlier article.

Title : Mercury Gas Holder.

Orig Pub : Pribery i tekhn. eksperimenta, 1956, No 1, 95-96

Abstract : The gas holder described is intended for the storage of expensive or poisonous gases. The construction of the gas holder makes it possible to work at absolute or relative pressure of 30 -- 200 mm mercury. It is possible to remove the gas completely from the gas holder by creating a vacuum. The gas holder can be used instead of a pump for the transfer of small quantities of gas. Gas holders with a geometric capacity of 5 -- 110 liters were constructed.

ZEL'DOVICH, A. G.

SUBJECT USSR / PHYSICS CARD 1 / 2 PA - 1498
 AUTHOR ZAVARICKIJ, N. V., ZEL'DOVICH, A. G.
 TITLE The Thermal Conductivity of Technical Material at Low Temperatures.
 PERIODICAL Zhurn. techn. fis., 26, fasc. 9, 2032-2036 (1956)
 Issued: 10 / 1956 reviewed: 10 / 1956

An apparatus is described here which serves the purpose of measuring thermal conductivity of solids within the range of from 2 to 100° K. By means of two thermometers the temperature distribution along the sample to be investigated was measured. The lower end of the sample was fitted with a pre-heater of manganite wire, the upper end was connected with a hydrogen- or helium bath by means of a cooling pipe. The upper end of the sample was connected with a second pre-heater, and for the purpose of extending the range of temperature a third pre-heater was in addition fitted. The thermometers were supplied by the firm of Allen-Bredly and had the form of thin plates which were cut out of graphite resistances. On both sides of these plates a layer of copper was electrolytically applied. The immediate change of thermal conductivity consisted in the determination of the resistances of the thermometers at different temperatures, on which occasion successively first one and then the other pre-heater was connected. Heroby it became possible to determine the drop of temperature along the sample. The mean error committed on the occasion of the determination of thermal conductivity amounted to 5% for the entire domain measured. The materials examined were copper as well as a number of copper alloys, duraluminium, noncorroding steel, and graphite. Measuring results are shown by diagrams. Among the samples examined there were such with both good and bad conductivity. The heat conductivity of

Žurn.techn.fis, 26, fasc.9, 2032-2036 (1956) CARD 2 / 2

PA - 1498

graphite at helium temperatures is about 100 times less than that of non-corroding steel and a few dozen times less than that of glass. In the case of an increase of admixtures heat conductivity modifies the character of its temperature dependence from $K \sim T$ to $K \sim T^2$, and, at the same time, the absolute value of heat conductivity is diminished. K denotes the average heat conductivity. This may be explained by the assumption that a transfer of heat takes place by the electrons and by the lattice in the metals. At sufficiently low temperatures the electronic part of heat conductivity is proportional to T , whereas the heat conductivity of the lattice in the metals is apparently proportional to T^2 because of phonon scattering on the electrons. In the case of pure metals the heat conductivity of the lattice in relation to the electron part of heat conductivity can be neglected because of its insignificance. However, in the case of alloys, heat transfer by the lattice begins to attain importance because the electron part diminishes. In conclusion the results obtained are compared with those obtained by other works.

TITLE: A Photographic Setup for Large Hydrogen Bubble Chambers
(Sistema fotografirovaniya dlya bol'shikh vodorodnykh
puzyr'kovykh kamer)

PERIODICAL: Priory i Tekhnika Eksperimenta, 1958, Nr 1, pp 38-41
(USSR)

ABSTRACT: A photographic setup for hydrogen bubble chambers of large dimensions is quite different from that for Wilson and diffusion chambers. In particular, a gas bubble in liquid hydrogen scatters light mainly in the forward direction, most of it between 0 and 10° , say (cf Fig.1) so that it is impossible to photograph the tracks at 90° to the incident light as is done in the usual chambers. For small bubble chambers the photographs may be taken with direct transmission in which the source of light is on the one side of the chamber and the photographic camera on the other (Refs.3-5). However, it is very difficult to use this system with a large hydrogen chamber since it is desirable not to employ large glasses as it is difficult to

Card 1/2 mount these on the main body of the chamber. The present

SOV-120-58-1-6/43

A Photographic Setup for Large Hydrogen Bubble Chambers.

authors have therefore developed a method of illuminating and photographing on one side of the chamber only. This method was tried on the working hydrogen chamber described in Ref.5 (this issue) and is shown in Fig.2. The back wall of the chamber was in the form of a spherical mirror, at the centre of curvature of which the source of light was placed. The light reflected from this mirror is focussed back again at the source and does not enter the objective of the photographic camera (B in Fig.2). The light which after reflection is scattered by the bubbles does enter the photographic camera and gives rise to the track images (Fig.3, facing p.35). The main disadvantage of this method is that in addition to the real images one gets the virtual images as well but these can be recognised by inspection or by a measurement of track co-ordinates by means of 2 stereo-photographs (the virtual image lies behind the mirror). A calculation of the scattered light as a function of angle,

International Conference on the Peaceful Uses of Atomic Energy. 2nd, Geneva, 1958

Booklet *svetitskikh isobrazheniy i primeneniye izotopov* (Reports of Soviet Scientists on the Production and Application of Isotopes) Moscow, Atomizdat, 1959. 368 p. (Series: *Ita*; Entry, vol. 6) 5,000 copies printed.

Book, (title page): O.V. Kuryumov, Academician, and I.I. Koryakov, Corresponding Member, USSR Academy of Sciences; Ed. (title book): L.N. Andreyenko; Tech. Ed.: L.N. Andreyenko.

PURPOSE: This book is intended for scientists, engineers, physicians, and biologists engaged in the production and application of atomic energy to peaceful uses; for professors and students and non-graduate students of higher technical schools where nuclear science is taught; and for the general public interested in atomic science and technology.

CONTENTS: This is volume 6 of a 6-volume set of reports delivered by Soviet scientists at the Second International Conference on the Peaceful Uses of Atomic Energy held in Geneva from September 1 to 13, 1958. Volume 6 contains 52 reports on 1) modern methods for the production of stable radioactive isotopes and their labeled compounds, 2) research results obtained with the aid of isotopes in the field of chemistry, metallurgy, medicine, biology, and agriculture, and 3) dosimetry of ionizing radiation. Volume 6 was edited by S.V. Levinsky, Candidate of Technical Sciences; V.N. Kuryumov, Candidate of Chemical Sciences; and V.Y. Podymov, Candidate of Technical Sciences. See 307/2881 for titles of volumes of the set. Entries appear at the end of the articles.

Separation of Deuterium From Hydrogen by Means of the Low-
temperature Distillation Method

PERIODICAL:

Kislod, 1959, Nr 6, pp 1 - 13 (USSR)

ABSTRACT:

The method mentioned in above title proved to be the most suitable and economical one for the production and preparation of deuterium. It was worked out and first applied on a large industrial scale in the USSR. In the present paper, a survey of the present state and problems connected with it in the USSR and abroad is given on the basis of published data. The main schemes of deuterium separation plants are represented and described in figures 1 and 2. The following problems are dealt with: rectification, heat emission, heat insulation, purification of hydrogen from impurities, and realization of the method in industry. There are 15 figures and 27 references, 8 of which are Soviet.

(Separation of Deuterium From Hydrogen by the Method of Deep
Freezing) Moscow, Gosatomizdat, 1961. 150 p. Errata slip
inserted. 4,000 copies printed.

Ed.: N. A. Korobtsova; Tech. Ed.: Ye I. Mazel'.

PURPOSE : This book is intended for scientists working on problems
of heavy water production, scientific and technical personnel
working on deep freezing problems and separation of isotopes,
instructors and advanced students.

COVERAGE: The book deals with the physical and technical principles
of deuterium separation from hydrogen by the deep freezing method.
The specificity of liquid hydrogen rectification is described along
with methods for the production of cold at the temperature level
of liquid hydrogen. The physicochemical constants of hydrogen
isotopes are presented in a form that is easy to use. The material

Buyanov, R. A., Zel'dovich, A. G., Pilipenko, Yu. K.

TITLE:

Some problems of catalytic production of liquid p-hydrogen

PERIODICAL:

Khimicheskaya promyshlennost', no. 2, 1961, 105-108

TEXT: Three methods of incorporating reaction vessels for catalytic production of p-hydrogen into the system of a hydrogen-liquefying plant are described. In the introduction, the purpose of producing p-H₂ is explained (long durability owing to low evaporation losses), as well as the use of hydrogen for producing deuterium, as charge for targets and bubble chambers and as rocket fuel. The three methods of incorporating reaction vessels are shown diagrammatically. Schemes a and b were elaborated at the kriogennaya laboratoriya (Cryogenic Laboratory) of the authors' Institute. Scheme b was proposed by A. B. Fradkov. In the liquefier of the type a, the hydrogen leaving the heat exchanger (1) of the cold zone under high pressure is branched into two currents. One part enters into the collecting vessel (4) for H₂ of normal composition (n-H₂) through throttle valve (8). The other part entering into cooling coil (3) through throttle valve (9) is liquefied

Card 1/5

Some problems of ...

entirely and supercooled owing to the effect of partial evaporation of $n\text{-H}_2$ in (4). From (3) H_2 enters into reaction vessel (2), where it is converted into $p\text{-H}_2$. Evaporation and heating by $3\text{-}4^\circ\text{K}$ sets in owing to the liberated heat of conversion. Dissipation of the heat of conversion and reliquefaction takes place in cooling coil (3). The pressure in the cooling coils is regulated by throttle capillaries. The $p\text{-H}_2$ flows through (10) into the collecting vessel (5), from where it is filled into Dewar vessels through valve (6). The $n\text{-H}_2$ vapor is drawn off through the countercurrent tubes of the heat exchanger. This variant does not warrant an isothermal course of the process and is therefore only suitable for the production of 92-93% $p\text{-H}_2$. In the type 6, reaction vessel (2) is designed as a coil and immersed into the collecting vessel (4) for $n\text{-H}_2$. Heat dissipation occurs not only in (3) but also through the walls of (2). This variant permits the production of 99.7% $p\text{-H}_2$. The hydrogen enters from (1) through valve (8) into the collecting vessel (5), where a pressure of 1.8 to 3.0 kg/cm^2 is maintained a helium valve (11). The vapor and the liquid $n\text{-H}_2$ flow through (11) into the collecting vessel (4), where the pressure is 0.5 kg/cm^2 , and is led back to

Card 2/5

89747

S/064/61/000/002/001/001
B101/B206

Some problems of ...

(1). The liquid H_2 enters from (5) into reaction vessel (2) and cooling coil (3), and is drained off as $p-H_2$ by means of valve (6). In the variant 6, the reaction vessel (2) is fed by a separate line with H_2 enriched with 49% $p-H_2$. The $n-H_2$ circulates separately and serves only as cooler. The H_2 to be converted is purified in adsorbers filled with active carbon and cooled by liquid N_2 . Partial conversion into $p-H_2$ sets in already here. Possibilities of incorporating such reaction vessels into existing hydrogen-liquefying plants are discussed, and it has been found that type 6 is suited for liquefiers of high and low capacity. Type 6 is suited for liquefiers of medium capacity (100-300 l/hr), which operate according to the refrigeration system. Type a is recommended for incorporation into liquefiers, where difficulties would arise when incorporating type 6. The following optimum conditions are given on the basis of experimental data (Refs. 2-5): charge of the reaction vessel with 30-120 g/hr of H_2 per cm^2 of cross section. The capacity of the liquefier drops by 33 to 35% when producing $p-H_2$. Chrome-nickel catalysts, $Fe(OH)_3$, $Cr(OH)_3$, and $Mn(OH)_4$ are mentioned as catalysts. As the Cr-Ni catalyst is difficult to activate (Refs. 4, 5) and can easily be poisoned by

Card 3/5

89747

B101/B206

Some problems of ...

O₂, it is only recommended for continuous operation. The hydroxide catalysts are activated at 0.1 mm Hg by heating them at 95 to 105°C for 24 hr. The poisoning by O₂ is reversible. If these catalysts are filled into the reaction vessel immediately after heating, their activity is reduced, so that twice as much must be taken. They can, however, be reactivated without heating, only in a vacuum. The required amount of the catalyst is calculated from the equation:

$V_H/V_k = 44.7K \left\{ \log \left[(1 - C_0/C_p) / (1 - C/C_p) \right] \right\}$, where V_H is the given capacity of the installation (1 p-H₂ per hr, with concentration C); V_k is the required volume of the catalyst, cm³; C_0 is the initial concentration of p-H₂ (25% as a rule); C_p is the equilibrium concentration of p-H₂ at the working temperature (99.8% as a rule); and K is the rate constant of the conversion reaction. The values of K for various catalysts are given in a table. There are 1 figure, 1 table, and 8 references: 5 Soviet-bloc and 3 non-Soviet-bloc.

TOPIC TAGS: bubble chamber, liquid hydrogen, para hydrogen, liquefaction technique, cryogenic device

ABSTRACT: The apparatus described is a Joule-Thomson liquifier based on a registered invention by the authors (Byulleten' izobreteniy No. 19 (1960), 18), and a smaller version was described by the authors earlier (PTE no. 2 (1961), 185 and no. 4 (1963), 191). A diagram of the liquifier is shown in Fig. 1 of the Enclosure. Its rated capacity is 200 liters of para-hydrogen per hour. The considerations governing the choice of some of the components of the equipment are discussed. Tables listing different characteristics for para-hydrogen production in the liquifier and of the design calculations are presented. Calculations based on the ex-

Card 1/3

perimental results show that the liquifier can work with 1500 m³/hr of compressed hydrogen and hence can produce 460 and 200 liters/hour of normal and para-hydrogen, respectively. "The authors thank N. K. Zel'dovich, A. A. Belushkina, L. P. Belonogova, A. A. Demin, and G. G. Khorev who took part in the design and assembly of the liquifier." SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 5, 1966, 44-45

TOPIC TAGS: bubble chamber, nuclear physics apparatus

ABSTRACT: This Author Certificate describes a bubble chamber consisting of a chamber surrounded by a vacuum mantle to which the windings of the electromagnet, the photographic and illuminating systems, and the shielding installation are fastened. To decrease the optical inhomogeneity of the liquid occupying the ballast volume of the chamber by cooling, the ballast chamber is equipped with a cooling coil. To prevent supercooling of the liquid in the working chamber, a heater is installed between the ballast and working chamber (see Fig. 1).

SOURCE: IVUZ. Radiofizika, v. 8, no. 3, 1965, 522-530

TOPIC TAGS: resonator, quantum resonance phenomenon, wave function, Cauchy problem 21, 44, 55

ABSTRACT: The modes of an open resonator are described by means of continuous spectrum wave functions of the type ψ_R developed in quantum mechanics. The modes themselves do not produce a complete orthogonal system. The ratio of the resonant to the nonresonant term in the selected functions is calculated. The limiting case of transition to an ideal closed resonator is presented. The field is broken down into oscillators and a system of wave functions for the continuous spectrum is selected. It is assumed that absorption by resonator walls does not take place and that the attenuation of the frequency modes is determined only by the radiation

UDC: 621.372

Card 1/2

L 6964-66

ACC NR: AP5020364

leaving the system. Properties of wave functions for the quasi-stationary states are considered in terms of the total system of functions. In this case the principal feature is the absence of spherical symmetry in an open resonator. The system of functions is also used to solve the Cauchy problem and the problem of external excitation at a given frequency. By displacing the integrating loop the resonant terms corresponding to the natural oscillations of the field are isolated. The method can be used to consider the forms of the spectral line for the spontaneous and induced radiations of an atom in an optical resonator. Orig. art. has: 25 formulas, 1 figure.

TITLE: Possible nonconservation of CP parity and nature of the $\Delta T = \frac{1}{2}$ rule

SOURCE: USSR. Gosudarstvennyy komitet po ispol'zovaniyu atomnoy energii. Institut teoreticheskoy i eksperimental'noy fiziki. Doklady, no. 343, 1965, Vozmozhnoye nesokhraneniye CP-chetnosti i priroda pravila $\Delta T = \frac{1}{2}$, 1-7

TOPIC TAGS: parity principle, K meson, lepton, particle interaction

ABSTRACT: It is known that the decay $K_2^0 \rightarrow 2\pi$ may be interpreted as the result of nonconservation of CP parity. Wolfenstein (1. Wolfenstein, Imaginary Fermi Constant G as a Model of CP Violation, CERN preprint 65/249/5 - Th. 525. 8.2.1965) has recently proposed a model in which the entire nonconservation of CP parity is due to an additional factor i in front of the Lagrangian of weak nonleptonic interaction with $\Delta Y = 1$. All the other terms of the weak interaction Lagrangian remain the same as in the standard current \times current theory. It is shown that two phenomena are tied together in Wolfenstein's model: the nonconservation of CP, and the $\Delta T = \frac{1}{2}$ rule for the Lagrangian of nonleptonic interaction with $|\Delta Y = \frac{1}{2}|$. Cer-

9

tain qualitative estimates of the scale of nonconservation of CP parity in amplitudes with $\Delta T = 1/2, 3/2$, and $5/2$ are made. From the observed probability of the decay $K_S^0 \rightarrow 2\pi$ it follows that CP-odd corrections to amplitudes with $\Delta T = 1/2$ amount to $10^{-3/2}$ (or even 10^{-4}). CP-odd corrections to amplitudes with $\Delta T = 3/2$ may be of the order of 2%, and to amplitudes with $\Delta T = 5/2$, about $10^{-2}\%$ if the transitions from $\Delta T = 3/2$ and $\Delta T = 5/2$ are comparable. "The authors are deeply grateful to I. Yu. Kobzarev, I. Ya. Pomeranchuk, and M. V. Terent'yev for many useful discussions of the problems touched upon in the paper." Changed Design of the Connecting Channel of Glass Furnaces
(Izmeneniye konstruktsii protoka steklovarenykh pechey)

PERIODICAL:

Steklo i keramika, 1959, Nr 8, pp 44-46 (USSR)

ABSTRACT:

The Kherson glass container plant has two tank furnaces operating on fuel oil. In 1958 furnace Nr 2 was reconstructed. The lining of the connecting channel as it is shown in figure 1, consisting of fire-clay beams, was exposed to great wear (fig 2). On the suggestion of Chief Engineer A. A. Safronov of the plant the lining of the connecting channels was made of mullite beams, and the channel as such was laid out as a dual channel, as can be seen in figure 3. furnace Nr 2 has been working faultlessly for 11 months, furnace Nr 1 for 7 months. Conclusion: it is advantageous to use mullite beams instead of the fire-clay beams used so far for the lining of connecting channels. Mullite beams have proven their practical value in operation. It would be desirable to have mass production of mullite adapting beams for connecting channels. There are 3 figures.

TITLE: Determination of the contact surface between metal and rolls during
piercing

PERIODICAL: Stal', no. 7, 1961, 626 - 629

TEXT: The metal pressure on the rolls during diagonal and longitudinal rolling can only be defined analytically when the contact surface between the metal and the roll is known. The calculation given by A. I. Tselikov [Ref. 3: Prokatnyye stany (Roll Stands), Metallurgizdat, 1946] for this contact surface in diagonal rolling does not supply sufficiently accurate data (as a rule lower values are obtained than the actual ones) in spite of applying corrections, because the ovalization of the billet section in the focus of deformation is not taken into consideration. When making allowance for this ovalization during rolling, before piercing and the displacement (s_x) of the section caused by the feed, an analytical formula can be established (Fig. 2) with which it is possible to determine the contact surface in any section of the deformation focus before the billet comes

Card 1/4

Determination of the contact surface between...

S/133/61/000/007/010/017
A054/A129

into contact with the mandrel;

$$b_{x+s} = \sqrt{\frac{D_{x+s}^2}{4} - \left[\frac{D_{x+s}}{2} - \frac{\xi_x^2 d_x^2 - d_{x+s}^2}{4(D_{x+s} + d_{x+s})} \right]^2} \quad (5)$$

where: b_{x+s} = the width of the contact surface before piercing, in the $x+s$ section, mm; D_{x+s} = diameter of the roll in the same section, mm; d_{x+s} = diameter of the billet in the $x+s$ section, mm; d_x = ditto, in section x , mm; ξ_x = coefficient of ovalization in section x . When not considering the effect of the incline angle of the roll, the distance between the roll axes can be regarded as being constant for the entire length of the deformation focus and in that case:

$$D_x + d_x = D_{x+s} + d_{x+s} = \dots = \text{const.} = D_n + b \quad (9)$$

D_n = roll diameter at the neck [Abstracter's note: subscript n (neck) is the translation of the Russian η (perezhim)]; b = distance between the rolls at the neck. By using $D_n + b$ instead of $D_{x+s} + d_{x+s}$ and $D_{x'+s'} + d_{x'+s'}$, the final equation for rolling without piercing will be:

Card 2/4

Determination of the contact surface between...

S/133/61/000/007/010/017
A054/A129

$$b_{x+s} = \sqrt{\frac{D_{x+s}^2}{4} - \left[\frac{D_{x+s}}{2} - \frac{\delta_{x+s}^2 - d_{x+s}^2}{4(D_n + b)} \right]^2} \quad (10)$$

and for rolling with mandrel (while making allowance for the displacement of the section after meeting the mandrel):

$$b_{x'+s'} = \sqrt{\frac{D_{x'+s'}^2}{4} - \left[\frac{D_{x'+s'}}{2} - \frac{\delta_{x'}^2 d_{x'}^2 + \delta_{x'+s'}^2 - \delta_{x'}^2 - d_{x'+s'}^2}{4(D_n + b)} \right]^2} \quad (11)$$

(where: $\delta_{x'}$, $\delta_{x'+s'}$ = the diameters of the mandrel in the x' and $x'+s'$ sections).
The correctness of the formulae given was proved by comparing the results with those obtained by Tselikov's method as well as with values actually measured. The calculation principles used for barrel-shaped rolls can also be applied to other types of diagonal rolling, for instance, to disk-shaped or tapered rolls. There are 5 figures, 2 tables and 5 Soviet-bloc references.

TITLE: Determination of axial forces acting on the mandrel
of a piercing mill

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy,
Chernaya metallurgiya, 1961, No.5, pp. 102-108

TEXT: The purpose of this work is to give an analytical
formula for the determination of axial forces acting on the
mandrel of a piercing mill. To derive this formula statics and
mathematical calculus are applied. The axial forces Q_I , Q_{II} , Q_{III}
acting on the mandrel in each region are expressed in terms of the
geometry of the mandrel, the friction coefficient existing between
the metal surface and the mandrel, and the reaction forces from
the rollers. Fig.1 shows the force diagram for the determination
of axial forces acting on the mandrel according to N.D. Lomakin
(Ref.5: N.D. Lomakin, "Determination of the axial forces acting on
the mandrel of a piercing mill. Metal working by pressure",
Collected articles under the editorship of N.P. Gromov, issue IV,
1956).

Determination of axial forces.....

S/148/61/000/005/004/015
E113/E180

In order to find the resultant of these forces for any shape that the generating curve of the mandrel may have, they are considered when acting on an elementary part of the generating curve. As an example the axial forces Q_1 and Q_2 are calculated for a mandrel having a spherical shape, using the theoretical approach developed. Axial force Q_{11} can be calculated from considerations of statics as in the region where it acts the generating curve of the mandrel is a straight line. It is necessary to note that not all of the force from the rolls is transmitted to the mandrel, but part of it is absorbed by the plastic bending of the walls of the rough-pierced tube. According to N.D. Lomakin the force necessary for plastic bending can be calculated according to the formula:

$$dP_{\text{bending}} = 0.8k_f \cdot \frac{(d_x - d'_x)^2}{d_x - d'_x} dx$$

where: k_f - resistance to plastic deformation; d_x, d'_x - external and internal diameters of the rough pierced tube at the section x . This formula is applied in the present work and with its aid, the

Card 2/5

Determination of axial forces.....

S/148/61/000/005/004/015
E113/E180

final form of formulae for the axial forces is derived. To check the correctness of the derived formulae, experiments have been carried out at Yuzhnotrubby zavod, one of the Soviet tube mills. In these experiments, the axial forces were measured for various cone angles of the rolls and various reductions at the tip of the mandrel. For the same values, the axial forces were calculated by means of the derived formula and are tabulated. Fairly good agreement between the theoretical and calculated values of axial forces can be observed. P.T. Yemel'yanenko, S.I. Borisov and A.I. Tselikov are mentioned in the paper. There are 3 figures, 1 table and 5 Soviet references.

TITLE: Application of Nuclear Resonance to Magnetic Measurements on a Synchrophasotron (Primeneniya yadernogo rezonansa pri magnitnykh izmereniyakh na sinkhrofazotrone)

PERIODICAL: Pribury i Tekhnika Eksperimenta, 1958, Nr 1, pp 50-53 (USSR)

ABSTRACT: An account is given of the application of nuclear magnetic resonance to magnetic measurements on an experimental 180 MeV synchrophasotron. In this experimental synchrophasotron the magnetic field varied between 400 and 10 500 oersted with a speed of 20×10^3 oersted per sec $\pm 3.5\%$. Variations in the speed of the change in the magnetic field were up to 20% and the non-uniformity of the field was $3.6 \times 10^{-3} \text{cm}^{-1}$. A number of circuits were developed for the recording of the nuclear magnetic resonance signal (Fig.1). The first two circuits in Fig.1 are used in the measurement of fields between 300 and 3000 oersted. The second of these circuits makes possible a remote control of the sensitivity. The third circuit in Fig.1 was used in the measurements of fields greater than 3000 oersted. The specimen used was water with 1% admixture of MnCl_2 or $\text{Fe}(\text{NO}_3)_3$. A general picture of the apparatus is shown in Fig.2. The stability of the resonance

Card 1/3

SOV-120-58-1-11/43

Application of Nuclear Resonance to Magnetic Measurements on a Synchrophasotron.

signals at 400 oersted was checked by having two identical setups. Over many days the difference between the two was never more than $\pm 0.05\%$ at 400 oersted and correspondingly better for higher fields. The apparatus was used on the synchrophasotron for the following purposes: (1) the determination of the law connecting the intensity of the magnetic field and the frequency of the accelerating voltage (Ref.1) and the verification of the stability of this relationship; (2) calibration in absolute units of the apparatus producing the magnetic field; (3) verification of the stability of this apparatus; (4) measurement of radial and asimuthal nonuniformity of the magnetic field; (5) measurement of the coefficient $n = r dH/H dr$ in different sections of the electromagnet; (6) studies of the stability of the relation between instantaneous values of the field in the different parts in the gap of the electromagnet; (7) verification of the stability of the relation between the fringe field and

TITLE: A Device for Measuring the Azimuthal Symmetry of the Field of Powerful Electromagnets (Izmeritel' azimuthal'noy simmetrii polya moshchnykh elektromagnitov)

PERIODICAL: Priory i Tekhnika Eksperimenta, 1958, Nr 1, pp 56-58 (USSR)

ABSTRACT: In order to study experimentally the intensity of the magnetic field in the gap of the electromagnet of the 680 MeV phasotron at the United Institute for Nuclear Studies, a special device was developed which can be used to determine rapidly the azimuthal symmetry in the median plane of the gap. When working the machine produces a magnetic field of 10-16 kOer while the maximum allowable deviation of the field from the average at the orbit is 0.5%. For this reason the instrument must have a sensitivity sufficient to be able to show changes less than 0.05% in the magnetic field. The device uses the variation of the magnetic permeability with magnetic field. Carbonyl iron was chosen as the working substance. The electronic circuit of the instrument is shown in Fig.1. The characteristic $\mu(H)$ was obtained using a high frequency oscillator. A coil whose core was made of carbonyl iron was

Card 1/3a part of the circuit of a valve oscillator and the change

SOV-120-58-1-13/43

A Device for Measuring the Azimuthal Symmetry of the Field of Powerful Electromagnets.

in μ was obtained from the change in the frequency of the output from the oscillator. In order to increase the sensitivity of the method, the method of beats was employed (cf. Fig. 1). The beats were obtained between the above oscillator and a quartz oscillator. The change in the beat frequency ΔF as the probe is displaced from a field H into a field $H + \Delta H$ is given by:

$$\Delta F = \alpha \Delta H \text{ or } \Delta H = \Delta F / \alpha$$

where α is the sensitivity. The dependence of α on H is shown in Fig. 2 and is roughly linear. A photograph of the device is shown in Fig. 3. Fig. 4 shows results of measurements of $\Delta H / H$ in per cent as a function of azimuth for different radii of the electromagnet of the phasotron. These curves show that the azimuthal symmetry of the magnetic field of the electromagnet of the phasotron is not worse

"On Measuring the Instantaneous Intensity Values Upon Varying the Magnetic Fields," by S. M. Rubchinskiy, M. P. Zel'dovich, and S. S. Kurochkin, Radiotekhnika i Elektronika, No 7, Jul 56, pp 1001-1013

A method of measuring the instantaneous value of intensity on varying the magnetic field was investigated and its results described (article is dated 25 June 1956).

The method of measuring was based on the phenomenon of nuclear magnetic resonance, and a device was developed suitable for the 10 Bev synchrophasotron at the Electrophysics Laboratory of the Academy of Sciences USSR.

TITLE: π^- - meson-neutron elastic backward scattering at 1.4-4.0 bev/c .

SOURCE: USSR. Gosudarstvennyy komitet po ispol'zovaniyu atomnoy energii. Institut teoreticheskoy i eksperimental'noy fiziki. Doklady, no. 350, 1965. π sup minus-meson-neutron elastic backward scattering at 1.4-4.0 Bev/c, 1-12

TOPIC TAGS: pion scattering, neutron scattering, elastic scattering, scattering cross section, angular distribution, spark chamber

ABSTRACT: The authors study the elastic backward scattering reaction

$\pi^- + n \rightarrow \pi^- + n$

in the 1.38-4.05 bev/c range. A spark chamber was used with photographic and neutron counter registration. The experimental installation was highly efficient in

recording γ -quantum from π^0 -decays, and the admixture of inelastic events

$\pi^- + n \rightarrow \pi^- + n + K\pi^{0+}$
in the 1700 cases of the elastic backward scattering reactions which were selected for study was no more than 2%. The solid angles for these cases were measured and the absolute cross sections were determined. Tables are given showing the cross section $\sigma_n = \sigma_{D^2O} - \sigma_{H_2O}$ and $R = \sigma_{H_2O}/\sigma_{D^2O}$ as functions of energy. The total error

in calculation of these cross sections due to necessary corrections for pion-pion and pion-neutron scattering in the ambient medium, electronic efficiency, beam composition and the shielding effect of nucleons in the deuterium was 25%. Data for σ_n and $\langle \sigma_n \rangle$ as functions of energy show some irregularity in the 2-3 bev region which may be due to resonance. Measurements of angular distribution for pion-neutron scattering show a minimum in the 162-180° region. The momentum transfer function is used as a basis for calculating the width of this minimum. A comparison of the experimental data obtained in this paper with those in the literature shows that the cross section $d\sigma/d\Omega$ is approximately inversely proportional to energy when the momentum transfer is constant. Orig. art. has: 4 figures, 2 tables.

TOPIC TAGS: pi meson, particle scatter, neutron scattering

ABSTRACT: The elastic backward scattering reaction $\pi^+n \rightarrow \pi^+n$ is studied in the 1.38-4.05 BeV/s pulse range. 1700 events of this reaction were selected with a pion scattering angle of $>90^\circ$. The solid angles for these events were measured (accuracy of measurement in the horizontal plane was 1° and in the vertical plane $\sim 5^\circ$). The results are given in graphic and tabular form. TITLE: Large scintillation counters and counters intended for operation in magnetic fields

SOURCE: Pribery i tekhnika eksperimenta, no. 4, 1966, 56-59

TOPIC TAGS: scintillation counter, particle counter

ABSTRACT: The results are reported of testing (a) large (up to 700 x 350 x 15 mm) scintillation counters with one photomultiplier and (b) long-lightguide counters capable of operating in strong magnetic fields. The large counters with 190--250-mm lightpipes were illuminated by a gamma beam from Cs¹³⁷; the irregularity of light collection was found to be 40% or less. The effect of the scintillation-crystal shape on the efficiency of particle recording was also explored. In the second type of counters, the ambient magnetic field was eliminated by either a compensating magnetic field derived from a special solenoid or by using lightguides long enough (1500--1800 mm) for locating the photomultiplier in a (50--100-cm) region permitting

TITLE: Large scintillation counters and counters for operation in magnetic fields

SOURCE: USSR. Gosudarstvennyy komitet po ispol'zovaniyu atomnoy energii. Institut teoreticheskoy i eksperimental'noy fiziki. Doklady, no. 373, 1965. Bol'shiye stsintillyatsionnyye schetchiki i schetchiki dlya raboty v magnitnykh polyakh, 1-16

TOPIC TAGS: scintillation counter, photomultiplier, ^{STRONG} magnetic field, light wave

ABSTRACT: Large scintillating counters and long light guides are essential for work in the area of strong magnetic fields. The authors have tested a variety of such counters in their experiments. The counters differed in shape and size of the crystals and length of light guides. In the case of each counter the authors determined the dependence of its effectiveness on the voltage of the photomultiplier and, in some cases, on the area of passage of particles through the scintillator. Measurements were conducted by studying cosmic rays and a beam generated by the ITEP accelerator under high load conditions. The signals from the counters entered the high-speed coincidence circuits. The resolution period of the circuits

Card 1/2

ACC NR: AT6001620

was 10-15 n sec. From the outputs of these circuits the standard signals proceeded to a slow coincidence circuit, which had a resolution of 10^{-7} sec. and an effectiveness of 100%. The experiments were conducted with large dimension counters, counters operating in strong magnetic fields, and counters with magnetic field compensation. Measurements of the amplitude spectrum of signals from the multipliers, taken with the magnetic field turned on and off, have shown that the activation of the magnetic field results only in an insignificant shift of the spectrum toward lower amplitudes (by 15-20%). The authors thank V. A. Lyubimova for her useful evaluations and Yu. V. Devyatikh, E. A. Strel'nikov, and V. D. Tarasova for their participation in the measurements. TITLE: Dilatometric anomalies in textured alloys during $\alpha \rightarrow \gamma$ transformation

SOURCE: Fizika metallov i metallovedeniye, v. 22, no. 6, 1966, 890-895

TOPIC TAGS: dilatometric anomaly, ferronickel alloy, ferromanganese alloy, austenite transformation, martensitic transformation / N12 ferronickel alloy, N15 ferronickel alloy, N23 ferronickel alloy, N28 ferronickel alloy, N32 ferronickel alloy, N27T2 Fe-Ni-Ti alloy, G7 ferromanganese alloy, G14 ferromanganese alloy

ABSTRACT: In textured Fe-Ni alloy the change in volume during $\alpha \rightarrow \gamma$ transformation of the martensitic type occurs nonisotropically. In particular, the transformation is accompanied by elongation of the alloy in the direction of the axis of texture although the specific volume of the γ -phase is smaller than that of the α -phase. In a statistically isotropic alloy the extent of the dilatometric (linear) effect during transformation reaches one-third of the volume effect; the same ratio exists between the linear and volume effects of transformation in an anisotropic material if the phase transition occurs in a crystallographically disordered manner.
